ABSTRACT

Aim: To determine the bi-caudate index (BCI) of Nigerians using computerized tomography from Sokoto North-Western Nigeria.

Study Design: Retrospective cross-sectional.

Place and Duration of Study: Department of Anatomy Usman Danfodiyo University Sokoto and Department of Radiology Usman Danfodiyo University Teaching Hospital Sokoto, between January, 2020 and January, 2022.

Methodology: CT scans of 186 apparently healthy normal individuals of age group 1 to 70 years were taken and the subjects were categorized into age intervals of 10 years; males and females taken separately. The linear measurements of caudate and brain were taken directly from the screen. The Bi Caudate Index were calculated. The mean values in each group were compared with age and sex, using appropriate statistical tests.

Results: The least BCI in male was 6.0mm and was seen in the age group 1-10 years while in female the least BCI was 5.0mm, seen in the age group 1-10. The largest BCI in male was 21mm, in the age group 61-70 years while in female the largest BCI was 17mm, seen in the age group 61-70 years.

*Corresponding author: E-mail: jibrinusman22@gmail.com;
observed in the age group 61-70 years, while the largest BCI in female 19.0mm, seen in the age group 61-70 years.

**Conclusion:** Bi Caudate Index shows positive correlation with age.

**Keywords:** Morphometry; bi-caudate; index; CT scan; Nigerians.

**1. INTRODUCTION**

“The need to study complete abnormal anatomies such as asymmetry causes interest for three- dimensional computed tomography (3D CT) to have risen over the last two decades” [1]. With Three dimensional computed tomography, contours and surfaces are rendered in fine detail” [2]. “There are several methods for measuring the brain, nuclei and brain ventricular sizes, which are applied as a means of evaluate brain atrophy during the normal aging process and diseases” [2].

“The digital CT scan machines currently in use also allow direct visualization of ventricles in cross sectional images and direct real time measurement of various dimensions of the ventricular system thus assisting in understanding the normal anatomy of the brain and its nuclei” [3]. “Morphometric analyses of caudate nuclei and cerebral ventricular system is essential for evaluating changes due to ageing, growth and various intrinsic and extrinsic pathologies” [4].

“The study of shape and size of brain nuclei has become a focus of interest in studies of some neuropsychiatric diseases like schizophrenia and Alzheimer’s disease” [5-7]. “Knowledge of anatomy of cerebral ventricular system is important for endoscopic neurosurgery” [8].

The caudate nuclei are grey matters that are situated deep in both the cerebral hemispheres. It consists of a head, body and tail [9].

The values of Bi- Caudate Index (BCI) varied between 0.08 and 0.23 with a mean value of 0.15±0.03 [10]. In a study done by the (BCI) was reported to be between 0.06 and 0.12 [11]. The bi-caudate index was considered to be abnormal if >0.17 and a definite enlargement if >0.20, and his values were between 0.06 and 0.19 with a mean value of 0.11±0.03 [12].

**2. MATERIALS AND METHODS**

This is a retrospective study of 178 normal brain CT scans of subjects from the Radiology Department of the Usman Danfodiyo University Teaching Hospital, whose ages ranged from 1 to 70 year. The CT scan images were retrieved from the hospital database. This study was conducted using CT images done between Jan 2020 and Jan 2022. The CT scans were done with NEUSOFT C 3000 Spiral CT machine Dual Slide Helical CT Scanner, (2005) model at 5mm slice thickness.

The images were viewed on the computer aided Digital Imaging and Communication in Medicine (DICOM) viewer using the RadiAnt Version 4.2 software. Measurements were taken to the nearest 0.1 millimeters.

The Bi Caudate indices were calculated from the linear measures taken at the level of intraventricular foramen as shown in Fig 1; The Bi Caudate indices were obtained by measuring the distance between the far lateral borders of the head of caudate at its mid-point at the level of interventricular foramen divided by the intracranial distance between the inner skull table at the same level in axial plane.

**Inclusion Criteria:** The Participants were from Nigeria, they are aged between 1 and 70 years and the brain CT scans were described as normal by a radiologist with respect to: a) Normal cerebral ventricular size, form, shape and periventricular translucency, b) brain parenchyma appears normal with no evidence of space occupying lesions and c) perfect positioning of the patient. With the Passage of the lowest tomographic section through a line 15–20 degrees to and 1cm above the cantho-mental line which represent the base of the skull.

**Exclusion Criterion:** The brain CT scans with these features were excluded from the study.

Evidence of space occupying lesions, cerebral hemorrhage, Previous brain trauma, seizures disorders, intellectual deterioration, alcoholism and dementia, asymmetry of the lateral ventricles, all brain CT scans with poor quality of the scan images.
Statistical analysis was done using Sigmasstat 2.0 for windows San Rafael CA. Statsoft (1995). Data are presented in tables and charts, and expressed as means and standard deviation. Differences in ventricular parameters with respect to sex were examined using Student's t test. One-way analysis of variance was used to analyze for variations across age groups and any significant correlation for the indices with the age using scatter diagram $P < 0.05$ was considered as statistically significant.

3. RESULTS AND DISCUSSION

3.1 Mean and SD of Bi-caudate Index (BCI) in Relation to Age and Sex

There is a gradual increase in the Bi-Caudate Index BCI from 2-4 years up to 70 years in both males and female. The BCI in males are generally larger than those of the females across all the age groups; but the differences are not statistically significant ($p >0.05$). The least BCI in male is 0.06cm and was seen in the age group 2-4 years while in female the least BCI is 0.05cm and was seen in the age group 5-10. The greatest BCI in male is 0.21cm and was observed in the age group 61-70 years, while greatest BCI in female is 0.19cm and was seen in the age group 61-70 years.

There was no statistical significant difference between sexes and same age groups as $p>0.05$.

3.2 Discussion

“As the human brain ages, characteristic structural changes occur that are considered to be normal and are expected. Thus the thorough knowledge of the age related normal changes that occur in the brain is required before any abnormal findings are analyzed” [14].

Bi-caudate index (BCI) was found to be more sensitive in showing the age changes than other linear ratios [4]. In this study we observed a gradual increase in the bi-caudate index from 1 year up to 70 years in both males and females. The BCI in males are generally larger than those of the females across all the age groups; but the differences are not statistically significant. The BCI varies from 6 mm to 21 mm in males and 5 mm to 19 mm in females. Similar findings were reported by Hahn and Rim who noted the values of BCI to vary between 8 mm and 23 mm with a mean value of 0.15±0.03 [10]. Ambili in a study among Indians reported Bi Caudate Index to vary between 0.06 cm and 0.12 cm [11]. Ambili reported a range of 0.06 cm to 0.20 cm with a mean value of 0.12±0.02 [13]. These findings corroborate with the finding in the current study.

“Whereas the age-related decline in gray matter volume is relatively linear from younger age to adulthood, the corresponding decline in white matter tends to be nonlinear, with a plateau in middle-age and additional decline, beyond that of gray matter, in late adulthood” [15].
“Several studies have used BCI to evaluate the caudate atrophy in patients with cerebral atrophy, Huntington’s chorea or in multiple sclerosis” [16-18]. “It has also been reported by some authors significant correlations between bicaudate index and duration of the Huntington’s chorea” [19]. This therefore place high significance in the method used in assessing the bicaudate index to enable patient with this medical abnormalities.

4. CONCLUSION

Base line data was provided in our environment with respect to bi-caudate index which can be used in assessing age-related decline in gray matter volume in relation to sex and to objectively judge ventricular dilatation by Radiologist, Neurologist, Neuro-surgeons and Psychiatrist to help in proper management of patient.

ETHICAL APPROVAL

As per international standard or university standard written ethical approval has been collected and preserved by the author(s).

CONSENT

As per international standard or university standard, patient(s) written consent has been collected and preserved by the author(s).

COMPETING INTERESTS

Authors have declared that no competing interests exist.
